Bluetongue (BT) is a disease of ruminants caused by the Bluetongue virus (BTV), transmitted by biting midges of the genus Culicoides, and considered endemic in many regions of Brazil. It is a notifiable disease to the World Organization for Animal Health (OIE), therefore its occurrence needs to be diagnosed and controlled to prevent economic damage for the animal transport, as well as losses due to clinical symptoms in susceptible hosts such as sheep and goats. To establish control programs, epidemiological information about the disease still needs to be established. The objective of this work was the study of insect collections to identifying Culicoides species with defined epidemiological importance and others that may be involved in the transmission of viruses. Combined identification keys were used in accordance with the specifications of the OIE reference laboratory for Bluetongue in Europe, evaluating collections previously obtained at the Biological Institute of São Paulo. From 2018 to 2019 23 samplings at six sites from two locations were assessed and a total of 407 Culicoides spp. was obtained. The highest number of Culicoides was reported in Cananeia municipality (56%). Considering both locations, the most abundant species identified was *C. insignis* (26 specimens). Five species of Culicoides spp. were identified, including *C. insignis*, which is the only species already proven as a vector for the BTV in Brazil. The training developed human resources for morphological identification of BTV vectors and will assist in the establishment of epidemiological vigilance in the State of São Paulo.
